Re: **Chicago Street (US-12), Road Diet Study**
City of Jonesville, Michigan

1 INTRODUCTION

This memorandum presents the results of the Road Diet Traffic Study for the West Chicago Street (US-12) corridor through the City of Jonesville, Michigan. The City of Jonesville is considering a road diet through restriping the existing five-lane sections of the West Chicago Street (US-12) corridor, between Walnut Street / Olds Street (M-99) on the west end and the existing three-lane section on the east end; the project limits are shown on **Figure 1**. The proposed road diet will reduce the roadway width to provide one-lane in each direction and maintain the existing two-way center left-turn lane (TWLTL). The primary goal of the proposed road diet is to improve safety for pedestrians and vehicles by reducing the crossing distance and reducing vehicle speeds by eliminating excess roadway capacity. Roadway information is summarized in **Table 1**. Additionally, F&V collected an inventory of existing lane use and traffic controls, as shown on the attached **Figure 2** and obtained existing traffic signal timing information from MDOT.

Table 1: Existing Roadway Information

Chicago Street Corridor	
Lane	5-lane (2 lanes each direction and TWLTL)
Average Daily Traffic (2019)	14,400 vpd
Functional Classification	Other Principal Arterial
Posted Speed Limit	30 mph

This study has been completed to examine the traffic operations and capacity, safety, and geometric needs of the corridor, including the following study intersections on West Chicago Street (US-12):

1. Walnut Street / Olds Street (M-99)
2. Water Street / West Street
3. Maumee Street / Evans Street (M-99)
4. East Street / Wright Street
5. Middle School Drive

The study includes the evaluation of the existing intersections operations and recommendations, including safety improvements, signal timing optimization along West Chicago Street (US-12), geometric improvements, and other measures that would be effective in improving the operations along the roadway corridor. The study analyses were completed using Synchro and SimTraffic (Version 11).

The study includes the evaluation of the following analysis scenarios:

Section 3: Baseline Conditions 2022

1. Existing Geometry (5-Lanes)
2. Road Diet (3-Lanes)
3. Road Diet (3-Lanes) with Improvements

Section 4: Horizon Year Conditions 2042

1. Existing Geometry (5-Lanes)
2. Road Diet (3-Lanes)
3. Road Diet (3-Lanes) with Improvements

2 DATA COLLECTION

The existing weekday turning movement traffic volume data were collected by F&V subconsultant Gewalt Hamilton Associates (GHA) on Thursday, March 17, 2022. Intersection Turning Movement Counts (TMC) were collected during the weekday AM (7:00 AM to 9:00 AM), MD (11:00 AM to 1:00 PM) and PM (2:00 PM to 6:00 PM) peak periods at all study intersections. The data collection included Peak Hour Factors (PHFs), pedestrian volumes, and commercial truck percentages which were used in the analysis in accordance with MDOT Electronic Traffic Control Device Guidelines. Peak hours at each intersection were utilized and through volumes were carried along the main study roadways and were balanced to determine the volumes at the site driveways in accordance with MDOT guidelines.

Due to the impact of COVID-19 and the subsequent closure of businesses and schools, current traffic volume data is not representative of "typical" operations. Therefore, historical traffic volume data was reviewed, and adjustment factors were determined to calculate baseline existing 2022 traffic volumes. A growth rate was applied to the historic volumes to calculate the expected 2022 traffic volumes. These were compared to the turning movement counts *collected*. The difference in the *expected* to the *collected* traffic counts is the COVID adjustment factor. The traffic volumes were then calculated by following the following process:

1. The existing 2022 peak hour traffic counts per intersection were identified
2. Peak hour COVID adjustments were applied to the raw data
3. The adjusted traffic volumes were then balanced to determine the balanced and COVID adjusted volumes used in the study.

COVID adjustment factors for the study roadway network are summarized in **Table 1** and the raw traffic volume data are attached. The baseline existing 2022 peak hour traffic volumes utilized in the study analyses are shown on the attached **Figure 3**.

Table 1: COVID Traffic Volume Adjustment Factors

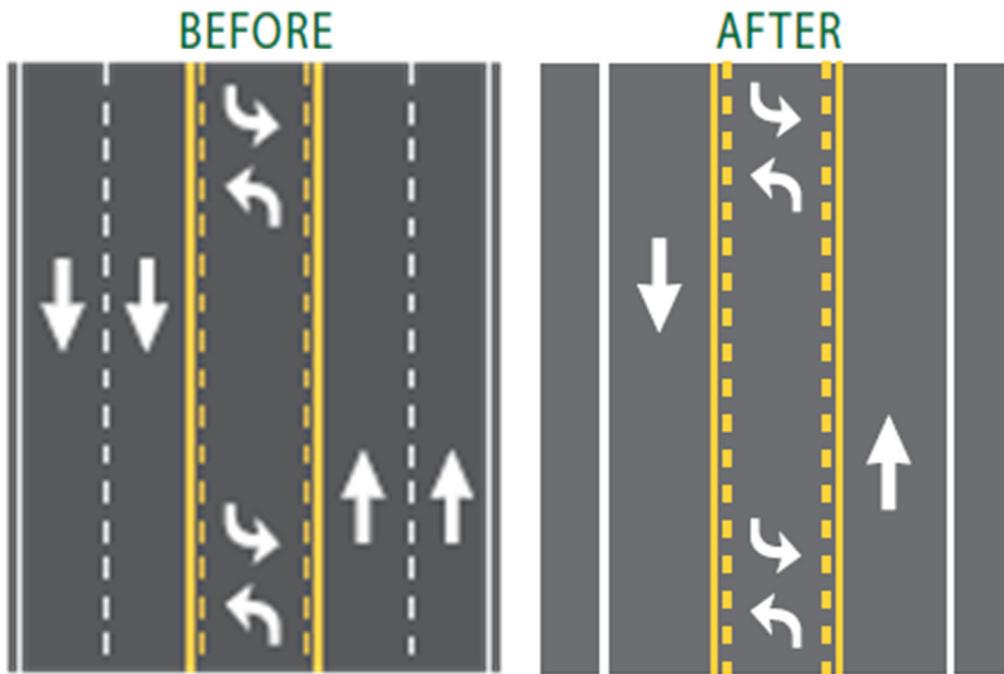

COVID Adjustment Factors	
AM	13%
MD	10%
PM	10%

3 BASELINE CONDITIONS (2022) ANALYSIS

The City of Jonesville is considering a road diet of the existing five-lane section of the West Chicago Street (US-12) corridor, between Walnut Street / Olds Street (M-99) to the west and the existing three-lane section to the east, as shown on the attached **Figure 1**. The proposed road diet will convert the existing five-lane section of West Chicago Street (US-12) into a three-lane roadway throughout the study corridor, with one (1) lane in each direction and a center two-way left-turn lane (TWLTL), as shown below in **Exhibit 1**.

Additionally, the roadway cross-section width that will be eliminated with the road diet and removal of the outside through lanes, between Walnut Street / Old Street (M-99) and the existing three-lane cross-section, is proposed to be converted to provide buffered bike lanes on both sides of the roadway.

Exhibit 1: West Chicago Street (US-12) – Roadway Cross-section

3.1 EXISTING GEOMETRY (5-LANES)

Analysis was performed to evaluate both the existing geometry and the proposed road diet geometry, with the existing 2022 traffic volumes. The peak hour vehicle delays and Levels of Service (LOS) were calculated at the study intersections using Synchro (Version 11) traffic analysis software and the methodologies presented in the *Highway Capacity Manual 6th, Edition* (HCM6). These analyses were performed based on the existing lane use and traffic control shown on the attached **Figure 2** and based on the proposed road diet geometry of reducing one (1) through lane in each direction. The existing peak hour traffic volumes used in the analysis are shown on the attached **Figure 3**.

Descriptions of LOS “A” through “F” as defined in the HCM6, are attached. Typically, LOS D is considered acceptable, with LOS A representing minimal delay and LOS F indicating failing conditions. SimTraffic network simulations were also reviewed to evaluate network operations and vehicle queueing throughout the study roadway network, as well as SimTraffic microsimulation projected delays. The results of the existing geometry analyses are attached and summarized in **Table 2**.

The results of the existing conditions analysis indicates that all approaches and movements at the study intersections are currently operating acceptably, at a LOS D or better during all peak periods (AM, MD, & PM) analyzed, with the exception of the following:

Walnut Street / Olds Street (M-99)

- The westbound through movement is currently operating at LOS F during the AM peak hour.

Although the Synchro intersection LOS analysis indicates poor operations during the AM peak hour, review of SimTraffic network simulation indicates generally acceptable operations throughout the study roadway network. The majority of vehicles were observed to be serviced within each cycle length; any persisting vehicle queues were observed to dissipate and were not present throughout the peak periods.

3.2 ROAD DIET (3-LANES)

The results of the road diet geometry analyses are attached and summarized in **Table 2**. The road diet geometry was compared to the existing geometry to determine what (if any) mitigation measures would be necessary to accommodate the road diet with the existing 2022 traffic volumes. The results of the analysis indicate that all study intersection approaches and movements currently operate acceptably, at a LOS D or better during all peak periods (AM, MD, & PM) analyzed, and are expected to continue operating acceptably with the implementation of the proposed road diet, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound shared through/right movement is expected to operate at LOS F during both the AM and PM peak hours.
- The westbound through movements are expected to operate at LOS F during the AM peak hour.

Chicago Street (US-12) & East Street / Wright Street

- The southbound approach is expected to operate at LOS E during the AM peak hour. Review of this intersection approach indicates delays during the AM peak hour, due to school traffic.

It should be noted that, with the implementation of a road diet along the study corridor, side street delays are expected to increase.

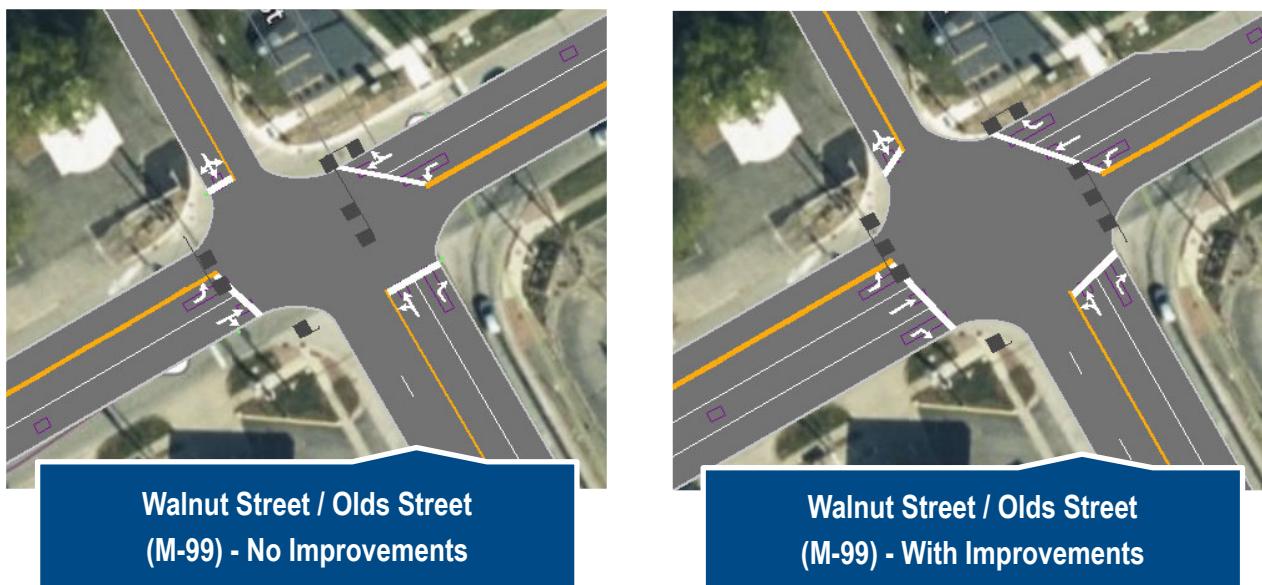

3.3 ROAD DIET WITH IMPROVEMENTS (3-LANES)

Mitigation measures were reviewed with the addition of the road diet, in order to improve the operations at Walnut Street / Olds Street (M-99). The recommended mitigation measures include the following.

- Signal timing optimization
- Restripe the eastbound and westbound approaches to provide exclusive right-turn lanes.

The recommended intersection geometry is shown below in **Exhibit 2**. Additionally, the recommended corridor intersection geometry is shown on the attached **Figure 4**.

Exhibit 2: Intersection Geometry – West Chicago Street (US-12) & Walnut Street / Old Street (M-99)

The results of the road diet geometry, with the implementation of the recommended improvements, are attached and summarized in **Table 3**. The results of the road diet (2022) with improvements analysis indicates that multiple study intersection approaches and movements at Chicago Street (US-12) & Walnut Street / Olds Street (M-99) will experience reductions in delay and improved LOS. Additionally, with the improvements implemented, all intersection approaches and movements are expected to operate acceptably, at a LOS D or better during all peak periods (AM, MD, & PM) analyzed, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound through movement is expected to operate at LOS E during the AM peak hour.

4 HORIZON YEAR (2042) ANALYSIS

Projected population growth rates for Hillsdale County, MI published by the Michigan Department of Technology, Management & Budget (DTMB) were used to calculate an annual background growth rate of 0.28%. Additionally, MDOT Planning provided a background growth rate of 0.2063% for the study corridor; however, the higher growth rate provided by DTMB was utilized for this study, as it provides a more conservative analysis. This background growth rate was applied to the existing 2022 traffic volumes to forecast the Horizon Year (2042) traffic volumes, as shown in the attached **Figure 5**.

4.1 EXISTING GEOMETRY (5-LANES)

The results of the existing geometry (horizon year 2042) analyses are attached and summarized in **Table 4** and indicate that all study intersection approaches and movements are expected to operate acceptably, at LOS D or better during all peak periods (AM, MD, & PM) analyzed, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The westbound through movement is expected to operate at LOS F during the AM peak hour. Additionally, the eastbound through and right-turn movements are expected to operate at LOS E.
- The northbound right-turn movement is expected to operate at LOS F during the PM peak hour.

4.2 ROAD DIET (3-LANES)

The results of the road diet geometry analyses are attached and summarized in **Table 4**. The road diet geometry was compared to the existing geometry to determine what (if any) mitigation measures would be necessary to accommodate the road diet with the horizon year (2042) traffic volumes. The results of the analysis indicate that most study intersection approaches and movements are expected to operate acceptably at a LOS D or better during all peak periods (AM, MD, & PM) analyzed and are expected to continue operating acceptably with the implementation of the proposed road diet, with the exception of the following.

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound shared through/right movement is expected to operate at LOS F during both the AM and PM peak hours.
- The westbound through movement is expected to operate at LOS F during the AM peak hour.
- The northbound right-turn movement is expected to operate at LOS F during the PM peak hour.

Chicago Street (US-12) & East Street / Wright Street

- The southbound approach is expected to operate at LOS F and LOS E during the AM and PM peak periods, respectively. Review of this intersection approach indicates delays during the AM peak hour, due to school traffic.

4.3 ROAD DIET WITH IMPROVEMENTS (3-LANES)

Mitigation measures were reviewed with the addition of the road diet, in order to improve the operations at Walnut Street / Olds Street (M-99). The recommended mitigation measures include the following.

- Signal timing optimization
- Restripe the eastbound and westbound approaches to provide an exclusive right-turn lanes.

The recommended corridor intersection geometry is shown on the attached **Figure 4**.

The results of the road diet geometry, with the implementation of the recommended improvements, are attached and summarized in **Table 5**. The results of the road diet (horizon year 2042) with improvements analysis indicates that multiple study intersection approaches and movements at Chicago Street (US-12) & Walnut Street / Olds Street (M-99) will experience reductions in delay and improved LOS. Additionally, with the improvements implemented, all intersection approaches and movements are expected to operate acceptably, at a LOS D or better during all peak periods (AM, MD, & PM) analyzed, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound through movement is expected to operate at LOS F during the AM peak hour.

5 MULTI-MODAL FACILITIES

The existing multi-modal facilities were reviewed as part of this study to determine the impacts on pedestrian and bicycle facilities with a road diet. The existing multi-modal facilities along the corridor are shown on the attached **Figure 6**. There are existing multi-modal facilities along the corridor including:

- Sidewalks on both sides of the roadway.
- Connectivity to the Jerry Russell Trail.
- Marked pedestrian crossings at all signalized intersections.
- Pedestrian signal heads and push buttons at all signalized intersections.
- Marked school crossing at Wright Street/ East Street.

Additionally, the roadway cross-section width that will be eliminated with the road diet and removal of the outside through lanes, between Walnut Street / Old Street (M-99) and the existing three-lane cross-section, is proposed to be converted to provide buffered bike lanes on both sides of the roadway.

Key findings of the review of the existing facilities are summarized below:

Jerry Russell Trail

The Jerry Russell trail runs generally in the north/south directions, located east of the Chicago Street (US-12) & Walnut Street / Olds Street (M-99) intersection. The trail crossing directs pedestrians and bicycles, wishing to cross Chicago Street (US-12), to the signalized intersection at Walnut Street / Olds Street (M-99). This is a detour of approximately 800-feet. During the 13-hour data collection (6:00 AM – 7:00 PM) 32 pedestrians crossed at the trail head crossing and 33 pedestrians crossed at the marked / signed signalized crossing. Based on this collected data, there is a noted desire for pedestrians to cross at the trail head location, rather than walking to the signal for a protected crossing; however, the data collected indicates a maximum hourly crossing volume of nine (9) pedestrians at the Jerry Russell Trail crossing, which is below the MDOT minimum pedestrian volume threshold, regardless of the pedestrian ages, which were not collected. Therefore, based on pedestrian volumes not meeting the MDOT minimum threshold, treatments and/or enhancements are not warranted at this pedestrian crossing location.

School Crossings

The pedestrian volumes were reviewed to determine the need for pedestrian crossing treatments along the study corridor. The analysis was performed in accordance with MDOT's *Guidance for Installation of Pedestrian Crosswalks on Michigan State Trunkline Highways*, as summarized below.

There is a designated school crossing at Wright Street / East Street intersection; however, through discussions with the City, they advised that the school district discourages students from using this crossing, due to the long (75-feet) unprotected crossing distance. Within the 6-hours of peak period data collection (AM, MD, and PM), a total of 13 pedestrians were recorded crossing at this location, while 40 pedestrians crossed at the adjacent signalized Evans Street / Maumee Street intersection.

Based on the pedestrian volumes, there is a desire for students to cross at the school crossing despite the school district discouraging crossing at this location. However, the data collection indicates a maximum hourly crossing volume of eight (8) pedestrians, which is below the MDOT minimum pedestrian volume threshold. Therefore, pedestrian crossing treatments and/or enhancements are not warranted at this location.

The MDOT minimum pedestrian volume for treatment at an uncontrolled crossing location is as follows:

- 20 pedestrians per hour* in any one hour, or
- 18 pedestrians per hour* in any two hours, or
- 15 pedestrians per hour* in any three hours, or
- 10 school age (grades K-12) pedestrians traveling to or from school in any one hour and the crossing in a designated school walking route

* Young, elderly, and disabled pedestrians count two times towards volume threshold

6 SAFETY STUDY

6.1 CRASH ANALYSIS

A crash analysis was conducted at the study intersections and roadway segments along the West Chicago Street (US-12) corridor. Historical traffic crash data was obtained from Michigan Traffic Crash Facts (MTCF). The crash analysis includes crashes from most recent five years (January 1, 2016, to December 31, 2020) of available data. There were a total 104 crashes reported along the study corridor in the past five years. There were 23 crashes with injuries, including seven (7) "Type B" injury crashes and two (2) fatalities.

A fatal crash occurred in April 2018 and involved three (3) vehicles. Vehicle 1 struck the right-rear of Vehicle 2 as they were turning into a driveway approximately 130 feet east of Olds Street. Vehicle 1 then lost control and struck Vehicle 3 going the opposite direction. The driver and passenger of Vehicle 1 were both killed. The crash report showed that alcohol was a contributing factor to the crash; additionally, neither the driver or passenger of Vehicle 1 were wearing seatbelts and no airbags deployed.

Another fatal crash occurred in August 2018 and involved two (2) vehicles. Vehicle 1 was travelling eastbound on West Chicago Street and struck the drivers-side of Vehicle 2 as they were turning out of a driveway approximately 300 feet east of Olds Street. The driver of Vehicle 2 was killed.

The general crash type along the corridor is Rear-End – Straight (32%), Sideswipe-Same Direction (24%), and Angle (22%) crashes. The majority of crashes at the signalized intersections are angle crashes and rear end crashes, which is typical of signalized intersections. Review of the UD-10 reports for these intersections indicate that the crashes were distributed equally from all directions of travel, suggesting that a directional crash pattern was not present. All the crashes included in this analysis are summarized in **Chart 1**. The individual intersection and segment crash types along the West Chicago Street (US-12) corridor are summarized in **Table 6**. Review of the summary data indicate that the majority of crashes occurred at the West Chicago Street (US-12) intersections with Walnut Street / Olds Street (M-99), Water Street / West Street, and Maumee Street / Evans Street (M-99).

6.2 HIGHWAY SAFETY MANUAL ANALYSIS

In order to determine the anticipated impact on safety, an analysis was performed according to the Highway Safety Manual (HSM) Empirical Bayes (EB) methodology. The analysis included the evaluation of the West Chicago Street (US-12) & Walnut Street / Olds Street (M-99) intersection with the following scenarios:

- Existing Geometry 2022 Volumes (5-Lanes)
- Road Diet 2022 Volumes (3-Lanes)

The latest HSM analysis spreadsheet, provided by the MDOT Safety Programs Unit, was utilized to determine the expected crashes associated with the existing and proposed road diet geometries. This analysis used the urban / sub-urban segments model and the crash prediction values provided in the HSM spreadsheet. The results of the analysis are summarized in **Table 11** and the detailed HSM summary sheets are attached.

The results of the analysis indicates that, with the implementation of the road diet, the total crashes are expected to increase; however, the fatal and injury (FI) crashes are expected to decrease. Therefore, the proposed road diet would result in safer overall conditions, with a smaller likelihood for motorists to get injured or killed.

Table 11: Highway Safety Analysis Summary

Analysis Scenario	Roadway	Segment	N _{Expected} (TOTAL)	N _{Expected} (FI)	N _{Expected} (PDO)
Existing 5-Lanes	Chicago St.	Walnut Street / Olds Street (M-99) to ECL	2.78	0.64	2.14
Proposed 3-Lnes	Chicago St.	Walnut Street / Olds Street (M-99) to ECL	2.82	0.62	2.20

7 CONCLUSIONS

The conclusions of this Traffic Study are as follows:

INTRODUCTION

The City of Jonesville is considering a road diet of the existing five-lane section of the West Chicago Street (US-12) corridor, between Walnut Street / Olds Street (M-99) to the west and the existing three-lane section to the east. The roadway cross-section width that will be eliminated with the road diet and removal of the outside through lanes, is proposed to be converted to provide buffered bike lanes on both sides of the roadway.

It should be noted that, with the implementation of a road diet along the study corridor, side street delays are expected to increase.

INTERSECTION OPERATIONS

All of the study intersections are expected to operate acceptably, at LOS D or better during all peak periods (AM, MD, and PM) analyzed, and are expected to continue operating acceptably with the implementation of the proposed road diet, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound shared through/right movement is expected to operate at LOS F during both the AM and PM peak hours.
- The westbound through movements are expected to operate at LOS F during the AM peak hour.

Chicago Street (US-12) & East Street / Wright Street

- The southbound approach is expected to operate at LOS E during the AM peak hour. Review of this intersection approach indicates delays during the AM peak hour, due to school traffic.

RECOMMENDED MITIGATION MEASURES

Mitigation measures were reviewed with the addition of the road diet, in order to improve the operations at Walnut Street / Olds Street (M-99). The recommended mitigation measures include the following.

- Signal timing optimization
- Restripe the eastbound and westbound approaches to provide exclusive right-turn lanes.

The results of the road diet (2022) with improvements analysis indicates that multiple study intersection approaches and movements at Chicago Street (US-12) & Walnut Street / Olds Street (M-99) will experience reductions in delay and improved LOS. Additionally, with the improvements implemented, all intersection approaches and movements are expected to operate acceptably, at a LOS D or better during all peak periods (AM, MD, & PM) analyzed, with the exception of the following:

Chicago Street (US-12) & Walnut Street / Olds Street (M-99)

- The eastbound through movement is expected to operate at LOS E during the AM peak hour.

MULTI-MODAL FACILITIES

The existing multi-modal facilities were reviewed as part of this study to determine the impacts on pedestrian and bicycle facilities with a road diet; key findings of the review are summarized below.

- There are two (2) uncontrolled pedestrian crossings along this corridor: one (1) at the Jerry Russell Trail and one (1) at Wright Street / East Street. The MDOT crosswalk guidance was evaluated.
- The results of the analysis indicates that the pedestrian volumes collected are below the MDOT minimum threshold; therefore, treatments and/or enhancements are not warranted at these location.

SAFETY STUDY

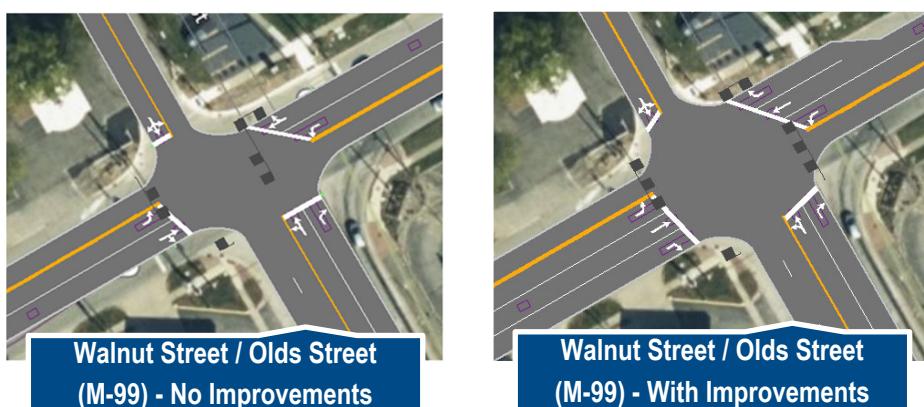

A crash analysis was conducted at the study intersections and roadway segments along the West Chicago Street (US-12) corridor. Key findings of the crash analysis are summarized below:

- There were a total 104 crashes reported along the study corridor in the past five years (January 1, 2016, to December 31, 2020).
- The majority of the crashes (87%) were intersection related, with 13% of the crashes related to the driveways. The general crash type along the corridor is Rear-End – Straight (32%), Sideswipe-Same Direction (24%), and Angle (21%) crashes.
- There were 24 crashes with injuries, including seven (7) "Type B" injury crashes and two (2) fatalities.

8 RECOMMENDATIONS

The primary goal of the proposed road diet is to improve safety by reducing the crossing distances and reducing vehicle speeds by eliminating excess roadway capacity. Recommendations for pavement markings and intersection layouts to improve pedestrian safety are shown in the attached conceptual design plans. The results of the analysis show that a road can be implemented along the corridor, with the following mitigation measures:

- Corridor signal timing optimization.
- Restripe the eastbound and westbound approaches at the Chicago Street (US 12) at Walnut Street / Olds Street (M-99) intersection. The recommended intersection geometry is shown below.

Any questions related to this memorandum, study, analyses, and results should be addressed to Fleis & VandenBrink.

Level of Service Criteria for Stop Sign Controlled Intersections

The level of service criteria are given in Exhibit 20-2. As used here, control delay is defined as the total elapsed time from the time a vehicle stops at the end of the queue until the vehicle departs from the stop line; this time includes the time required for the vehicle to travel from the last-in-queue position to the first-in-queue position, including deceleration of vehicles from free-flow speed to the speed of vehicles in queue.

The average total delay for any particular movement is a function of the number of vehicles in the queue, the number of vehicles per hour, and the critical gap size. The critical gap size is the minimum gap required for a driver to stop safely. The number of vehicles per hour is the traffic volume. The average total delay is calculated as:

$$D = \frac{V}{C} + \frac{Q}{C} \cdot \frac{1}{G}$$

Where D is the average total delay, V is the traffic volume, C is the critical gap size, and Q is the number of vehicles in the queue. If there are no signals present on the major street, upstream of the subject intersection, flows may not be random but will likely have some platoon structure. Although the procedures in this chapter provide a method for approximating the operations of a TWSC intersection with an upstream signal, the operations of such an intersection is arguably best handled by including it in a complete simulation.

Exhibit 20-2. Level of Service Criteria for Stop-Controlled Intersections (Motor Vehicles)

LEVEL OF SERVICE	AVERAGE CONTROL DELAY (sec/veh)
A	≤ 10
B	> 10 and ≤ 15
C	> 15 and ≤ 25
D	> 25 and ≤ 35
E	> 35 and ≤ 50
F	> 50

Average total delay less than 10 sec/veh is defined as Level of Service (LOS) A. Follow-up times of less than 5 sec have been measured when there is no conflicting traffic for a minor street movement, so control delays of less than 10 sec/veh are appropriate for low flow conditions. A total delay of 50 sec/veh is assumed as the break point between LOS E and F.

Additionally, several driver behavior considerations combine to make delays at signalized intersections less onerous than at unsignalized intersections. For example, drivers at signalized intersections are able to relax during the red interval, where drivers on the minor approaches to unsignalized intersections must remain attentive to the task of identifying acceptable gaps and vehicle conflicts. Also, there is often much more variability in the amount of delay experienced by individual drivers at unsignalized than signalized intersections. For these reasons, it is considered that the total delay threshold for any given level of service is less for an unsignalized intersection than for a signalized intersection.

LOS F exists when there are insufficient gaps of suitable size to allow a side street demand to cross safely through a major street traffic stream. This level of service is generally evident from extremely long total delays experienced by side street traffic and by queueing on the minor approaches. The method, however, is based on a constant critical gap size - that is, the critical gap remains constant, no matter how long the side street motorist waits. LOS F may also appear in the form of side street vehicles' selecting smaller-than-usual gaps. In such cases, safety may be a problem and some disruption to the major traffic stream may result. It is important to note that LOS F may not always result in long queues but may result in adjustments to normal gap acceptance behavior. The latter is more difficult to observe on the field than queueing, which is more obvious.

Level of Service for Signalized Intersections

Level of service for signalized intersections is defined in terms of delay, which is a measure of driver discomfort and frustration, fuel consumption, and lost travel time. LOS can be characterized for the entire intersection, each intersection approach, and each lane group. Specifically, level-of-service (LOS) criteria are stated in terms of the average stopped delay per vehicle. The criteria are given in Exhibit 19-8. Delay may be measured in the field or estimated using procedures presented later in this chapter. Delay is a complex measure and is dependent on a number of variables, including the quality of progression, the cycle length, the green ratio, and the v/c ratio for the lane group in question.

LOS A describes operations with a control delay of 10 s/veh or less. This level is typically assigned when the volume-to-capacity ratio is low and either progression is extremely favorable or the cycle length is very short. If LOS A is the result of favorable progression, most vehicles arrive during a green indication and travel through the intersection without stopping.

LOS B describes operations with control delay between 10 and 20 s/veh. This level is typically assigned when the volume-to-capacity ratio is low and either progression is highly favorable or the cycle length is short. More vehicles stop than with LOS A.

Exhibit 19.8. Level-of-Service Criteria for Signalized Intersections (Motorized Vehicles)

LEVEL OF SERVICE	STOPPED DELAY PER VEHICLE (SEC)
A	≤ 10.0
B	> 10.0 and ≤ 20.0
C	> 20.0 and ≤ 35.0
D	> 35.0 and ≤ 55.0
E	> 55.0 and ≤ 80.0
F	> 80.0

1. If the v/c ratio for a lane group exceeds 1.0, a LOS F is assigned to the individual lane group. LOS for approach-based and intersection-wide assessments are determined solely by the control delay.

LOS C describes operations with control delay between 20 and 35 s/veh. This level is typically assigned when progression is favorable or the cycle length is moderate. Individual *cycle failures* (i.e. one or more queued vehicles are not able to depart as a result of insufficient capacity during the cycle) may begin to appear at this level. The number of vehicle stopping is significant, although many vehicles still pass through the intersection without stopping.

LOS D describes operations with control delay between 35 and 55 s/veh. This level is typically assigned when the volume-to-capacity ratio is high and either progression is ineffective or the cycle length is long. Many vehicles stop and individual cycle failures are noticeable.

LOS E describes operations with control delay between 55 and 80 s/veh. This level is typically assigned when the volume-to-capacity ratio is high, progression is unfavorable, and the cycle length is long. Individual cycle failures are frequent.

LOS F describes operations with control delay exceeding 80 s/veh or a volume-to-capacity ratio greater than 1.0. This level, considered to be unacceptable to most drivers, often occurs with over-saturation, that is, when arrival flow rates exceed the capacity of the intersection. This level is typically assigned when the volume-to-capacity ratio is high, progression is very poor, and the cycle length is long. Most cycles fail to clear the queue.
